The Goal of investigation

The goal of this work is to demonstrate developed mathematical model of the flow, numerical algorithm and a software package in order to estimate the influence exerted on the aircraft characteristics by user-specified input parameters.

The investigations were carried out using a specially developed mathematical model and created three-dimensional hydrodynamic code, designed to simulate two components turbulent compressed gas flows around the aircraft.
The Complexity of the Problem

• The flow is essentially three-dimensional and turbulent and, in the general case, can be of mixed type (sub- and supersonic).

• The computational domain has to be large, which is required for the flow characteristics near the aircraft to be reliably determined.

• Relatively narrow boundary layers developing on the aircraft surface have to be resolved.

• The moving medium is multicomponent. In the general case, this is a mixture of fuel combustion products and the ambient air flowing past the aircraft.
Mathematical Models of the Code

- The three-dimensional unsteady Reynolds-averaged compressible Navier-Stokes equations, closed with a model of eddy viscosity and thermal conductivity (RANS model).

- The equations for determining the turbulent flow parameters that allow to calculate turbulent exchange coefficients.

- The equation for determining the concentration of combustion products in a mixture of air--combustion of hydrocarbon fuel.

- Boundary conditions for all functions that define the time and spatial characteristics of gas flow.
Basic Equations

\[
\frac{\partial p}{\partial t} + \nabla \cdot (\rho u) = 0
\]

\[
\frac{\partial p u_i}{\partial t} + \nabla \cdot (\rho u_i u) + \frac{\partial p}{\partial x_i} = \sum_{j=1}^{3} \frac{\partial \tau_{ij}}{\partial x_j}
\]

\[
\frac{\partial}{\partial t} (\rho E) + \nabla \cdot (\rho H u) = \sum_{i,j=1}^{3} \frac{\partial u_j}{\partial x_i} \tau_{ji} + \nabla \cdot \left( k_{\Sigma} \nabla T \right)
\]

\[
\tau_{ij} = -2\mu_{\Sigma} \nabla \cdot u + \mu_{\Sigma} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)
\]

\[
E = \int_{T_0}^{T} C_V \left( T' \right) dT' + e_0 + \frac{1}{2} \sum_{i=1}^{3} u_i^2 , \quad H = \int_{T_0}^{T} C_P \left( T' \right) dT' + h_0 + \frac{1}{2} \sum_{i=1}^{3} u_i^2
\]

- $\mu_{\Sigma}$ and $k_{\Sigma}$ – effective viscosity and heat conductivity coefficients
- $C_V$ and $C_P$ – heat capacity at constant volume and pressure
- $e_0$ and $h_0$ – energy and specific enthalpy of medium at temperature $T_0$
State Equation
(смесь совершенных газов)

\[ p = R_0 \rho T \left( \frac{1 - \beta}{\nu_1} + \frac{\beta}{\nu_2} \right) \]

\[ C_p = (1 - \beta) C_{p1} + \beta C_{p2} \]

\[ k_{\Sigma} = C_p \left( \frac{\mu}{Pr} + \frac{\mu_T}{Pr_T} \right) \]

- \( R_0 \) – the universal gas constant
- \( \nu_i, C_{P_i} \) – molar masses and heat capacities of the combustion gases
- \( \beta \) – mass fraction of the combustion products in the mixture
- \( \mu, \mu_T \) – the molecular and eddy viscosities of the mixture
- \( Pr, Pr_T \) – laminar and turbulent Prandtl numbers
Two parameters turbulent Coacley’s $q$–$\omega$ model

\[ \frac{\partial \rho q}{\partial t} + \nabla \cdot (\rho q \mathbf{u}) = \nabla \cdot \left( \mu_{\Sigma q} \nabla q \right) + \frac{\rho q}{2\omega} \left( C_{\mu} f D - \frac{2}{3} \omega \nabla \cdot \mathbf{u} - \omega^2 \right) \]

\[ \frac{\partial \rho \omega}{\partial t} + \nabla \cdot (\rho \omega \mathbf{u}) = \nabla \cdot \left( \mu_{\Sigma \omega} \nabla \omega \right) + \rho \left[ C_{1} \left( C_{\mu} D - \frac{2}{3} \omega \nabla \cdot \mathbf{u} \right) - C_{2} \omega^2 \right] \]

\[ D = \sum_{i,j=1}^{3} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right)^2 - \frac{2}{3} (\nabla \cdot \mathbf{u})^2, \quad q \rightarrow \text{«pseudovelocity} \quad \omega \rightarrow \text{«pseudovorticity} \]

\[ \mu_{\Sigma \omega} = \mu + 1.3 \mu_{T}, \quad \mu_{\Sigma q} = \mu + \mu_{T}, \]

\[ \mu_{T} = C_{\mu} f(n) \rho \frac{q^2}{\omega}, \quad f(n) = 1 - \exp \left( -0.0065 \frac{\rho q n}{\mu} \right), \]

\[ C_{1} = 0.045 + 0.405 f(n), \quad C_{2} = 0.92, \quad C_{\mu} = 0.09 \]
Substance Mixing model

\[
\frac{\partial C_a}{\partial t} + \frac{\partial}{\partial x}\left(uC_a - D_\Sigma \frac{\partial C_a}{\partial x}\right) + \frac{\partial}{\partial y}\left(vC_a - D_\Sigma \frac{\partial C_a}{\partial y}\right) + \frac{\partial}{\partial z}\left(wC_a - D_\Sigma \frac{\partial C_a}{\partial z}\right) = 0
\]

\[
D_\Sigma = \frac{1}{\rho} \left( \frac{\mu}{Sc} + \frac{\mu_T}{Sc_T} \right)
\]

\[
\beta = \frac{C_a}{\rho} \quad \text{– mass fraction of the combustion products in the mixture}
\]

\[
C_a \quad \text{– mass concentration of bastion products at point}
\]

\[
D_\Sigma \quad \text{– effective diffusion coefficient}
\]

\[
Sc, \ Sc_T \quad \text{– laminar and turbulent Schmidt numbers}
\]
Computational Algorithm

Conservative Approximation of Spatial Operators

The approximations of the spatial operators used in the algorithm are described as applied to the Navier-Stokes equations. These approximations are underlain by the following identities, which are often used as definitions of the corresponding operators:

$$\text{div} \, \mathbf{g} = -\lim_{\Omega \to 0} \frac{\oint_{\partial \Omega} \mathbf{g} \cdot \mathbf{n} \, d\Gamma}{|\Omega|},$$

$$\text{grad} \, p = -\lim_{\Omega \to 0} \frac{\oint_{\partial \Omega} p \mathbf{n} \cdot d\Gamma}{|\Omega|},$$
Approximation of Viscous Operators

\[ J(V) = \int_{\Omega} [I(V) - 2(V \cdot \Theta)] dxdydz \]

\[ I(V) = \mu \left[ \frac{4}{3} (u_x^2 + v_y^2 + w_z^2 - u_x v_y - v_y w_z - u_x w_z) + (u_y + v_x)^2 + (u_z + w_x)^2 + (v_y + w_y)^2 \right] \]
Implicit Scheme and Iterative Algorithm

Governing Equations are numerically solved using a two-level fully implicit difference scheme of the form

\[
\frac{\phi^k - \phi^{k-1}}{\Delta t} + A^{-1}H(\phi^k) = 0,
\]

\[
H(\phi^k) = T(\phi^k) + V(\phi^k).
\]

\[
A = E + \frac{1}{d}\tilde{V}', \quad d = \|T'\|,
\]

\(\phi\) – grid vector function involving all unknown functions

\(k\) – the time level index

\(\Delta t\) – time step; \(A\) – operator improving the convergence of the iterations

\(H\) – operator containing all spatial difference derivatives
The grid algorithm generates a three-dimensional boundary-conforming structured meshes with hexahedral cells. Degenerate (pentahedral) cells could be used on the axis of symmetry of the domain.
Grid Requirements

1) The mapping to a parametric parallelepiped used in structured mesh generation must be continuously differentiable and its Jacobian must not vanish.

2) To resolve the boundary layers, the mesh must be refined toward the solid walls. Moreover, the transverse (to the flow direction) mesh size near these surfaces can be $10^{-4}$ and less of the characteristic length of the problem.

3) The grid lines near the walls must be nearly orthogonal to them. Wherever possible, the mesh cells must be similar to parallelepipeds.

4) The numerical grid must be quasi-uniform in the sense that, as the number of grid nodes tends to infinity, the difference between the characteristic lengths of neighboring cells tends to zero faster than the lengths themselves. Anyway, the ratio of the characteristic lengths of neighboring cells must not be too large.

It is assumed that fuel combustion products are exhausted from the nozzle of the vehicle. The exhaust jet has a high temperature. In the general case, the physical characteristics of the jet differ noticeably from those of the ambient air. The task is to determine the flow parameters near the vehicle and some of its integral characteristics.

Three-Dimensional Turbulent Gas Flows in Complex Nozzle Systems
Temperature distribution in the middle section
Streamlines in a vertical plane through the interwall spacing
Streamlines for the flow behind the nozzle exit
Simulation of gas flow in cooled axial turbines

Numerical grid in middle radial and axial plans
Temperature in first stage stator of turbine in middle radial and axial plans.
Mach number in first stage rotor of turbine in middle radial and axial plans
CONCLUSIONS

The submitted results show the ability to use the software package for solving wide range of stationary and non-stationary aerodynamic problems.
THANK YOU FOR ATTANTION
